Test Plan / Strategy Document

Overview

This document outlines the testing strategy for the Shopping Cart API of the Practice Software Testing platform. The goal is to validate that cart-related endpoints behave as expected under standard and error conditions.

What is Being Tested

The following Cart API operations are being tested:

- Creating a cart
- Retrieving a cart by ID
- Adding items to a cart
- Deleting a cart
- Handling of invalid requests and methods

Test Coverage Areas

Area	Description
Functional Testing	Verify endpoints behave according to specifications
Negative Testing	Test responses for invalid inputs and unsupported methods
Data Validation	Check that returned data matches expected structure and values
Status Code Validation	Ensure correct HTTP codes are returned (e.g., 200, 404, 405)
Dynamic Variable Management	Validate use of variables like {{Cart_ID}} across requests
Response Schema Validation	Ensure required fields are present in response (e.g., id)

Tools Used and Why

Tool	Purpose
Postman	Manual and automated API testing
Postman CLI	Command-line execution of Postman tests

Assumptions

- Base API URL: <https://api.practicesoftwaretesting.com/>
- All endpoints return valid JSON responses.
- Cart creation response includes a unique id (stored as Cart_ID).
- The API does not require authentication for basic operations.

Limitations

- Tests do not include database or backend validation (black-box only).
- No automated mocking or sandboxing is in place.
- API downtime or changes may break tests.
- Limited to HTTP-based functional testing only (no performance/load tests).
